Nomenclature

ρ_m	linear mass density
$\rho_{m_{booster}}$	linear mass density of the booster
$\rho_{m_{dart}}$	linear mass density of the dart
E_i	Young modulus of beam i
F_i	external force along z-axis applied on node i
G	center of gravity
$I_{G,y,i}$ or I_i	second moment of area of beam i
$I_{G,y_{booster}}$	second moment of area of the booster about the neutral axis along the y-axis
$I_{G,y_{dart}}$	second moment of area of the dart about the neutral axis along the y-axis
$I_{G,y}$	second moment of area about the neutral axis along the y-axis

L	missile length
l	length of an element beam
m	missile mass
m_i	mass of node i
$M_{y,i}$	external moment along y-axis applied on node i
n	number of nodes
E	longitudinal Young modulus of the missile

1 Structural Model

1.1 From continuous to discrete

ASTER-30 length is 4.9 m and the largest diameter is 0.36 m on the booster so the missile can be considered as a beam with variable cross section. Euler-Bernoulli beam theory is suitable here because higher order models like Timoshenko beam theory would bring additive complexity and precision that are not needed for this study. Therefore sections rotational inertia and shear deformation are neglected. For the purpose of this study, only bending along y-axis is considered so deformations of the missile are contained in the zx-plane.

During the acceleration phase, ASTER-30 is composed of two parts: the booster and the dart. Both of them can be modeled as cylindrical pipes. The booster section has a diameter of 36 cm and the dart is 18 cm wide. The skin thickness¹ of the missile is 2 mm. These dimensions are illustrated in Figure 1.

The material used for the missile is assumed to be 30% carbon fibres composites and unidirectional along the longitudinal axis. The Young modulus along the x-axis is $E = 180 \text{ GPa}$ for such a material. The second moment of area at the neutral axis along y-axis for a cylindrical section is:

$$I_{G,y} = \pi \frac{D^4 - (D - 2e)^4}{64}$$

with D and e the external diameter and thickness of the pipe. Thus, the second moment of area for the booster and the dart are :

$$\begin{cases} I_{G,y_{booster}} &= 3.60 \cdot 10^{-5} \text{ m}^4 \\ I_{G,y_{dart}} &= 4.43 \cdot 10^{-6} \text{ m}^4 \end{cases}$$

¹Estimated from the natural frequency of the 1st bending mode at 20Hz

Figure 1: ASTER-30 Dimensions

Figure 2: Lumped Element Model of a Beam (5 nodes)

It is assumed that the missile mass is equally distributed in the dart and in the booster therefore the linear mass density ρ_m is uniform in the booster, and uniform in the dart:

$$\begin{cases} \rho_{m_{\text{booster}}} &= 140.9 \text{ kg.m}^{-1} \\ \rho_{m_{\text{dart}}} &= 51.9 \text{ kg.m}^{-1} \end{cases}$$

It is necessary to discretize the body in order to be able to conduct a state-space representation and simulations. To reach this goal, the mathematical model of the structure is designed using a lumped element model illustrated in Figure 2.

Geometry The missile is longitudinally discretized in n nodes evenly spaced by the beams length $l = \frac{L}{n-1}$. The nodes i and $i+1$ are linked together by a massless Euler-Bernoulli beam i . Let z_i , \dot{z}_i and \ddot{z}_i be respectively the displacement, speed and acceleration of node i along the z -axis. θ_i , $\dot{\theta}_i$ and $\ddot{\theta}_i$ are respectively the pitch angle, pitch rate and pitch acceleration of the beams at the junction node i .

Figure 3: Computed First Mode Natural Frequency

To determine the number of nodes needed, we can consider looking at the natural frequencies of the beam converging as n grows. On Figure 3, first structural mode frequencies have been computed² for n varying between 7 and 300. The frequency converges when n increases. Eventually $n = 100$ is a good choice to minimize the number of nodes for computational efficiency and having an acceptable accuracy on natural frequencies. Indeed, at about $n = 100$, the frequency oscillates between 19.85 Hz and 20.15 Hz which corresponds to 1.5% of variation. It is worth noting that the uncertainty on the real first mode frequency is 5 to 10% so with $n = 100$, the first mode frequency can be said as converged.

Mass and stiffness Each node $i \in \llbracket 1, n \rrbracket$ has a point mass m_i that is the mass of the section from $x = (i - \frac{3}{2})l$ to $x = (i - \frac{1}{2})l$. Thus the mass is conserved during the discretization : $\sum_{i=1}^n m_i = m$. The Euler-Bernoulli beam i has a Young modulus E_i and the second moment of area at neutral axis passing through G and along y-axis $I_{G,y,i}$. For readability purposes, $I_{G,y,i}$ will be noted I_i but the reader must be careful not to confuse it with a rotational inertia, generally noted J in this paper.

The different structural parameters of the body are summarized in Figure 4 for $n = 100$. It is clear that the booster is stiffer and heavier than the dart.

²The method to do so will be explained later.

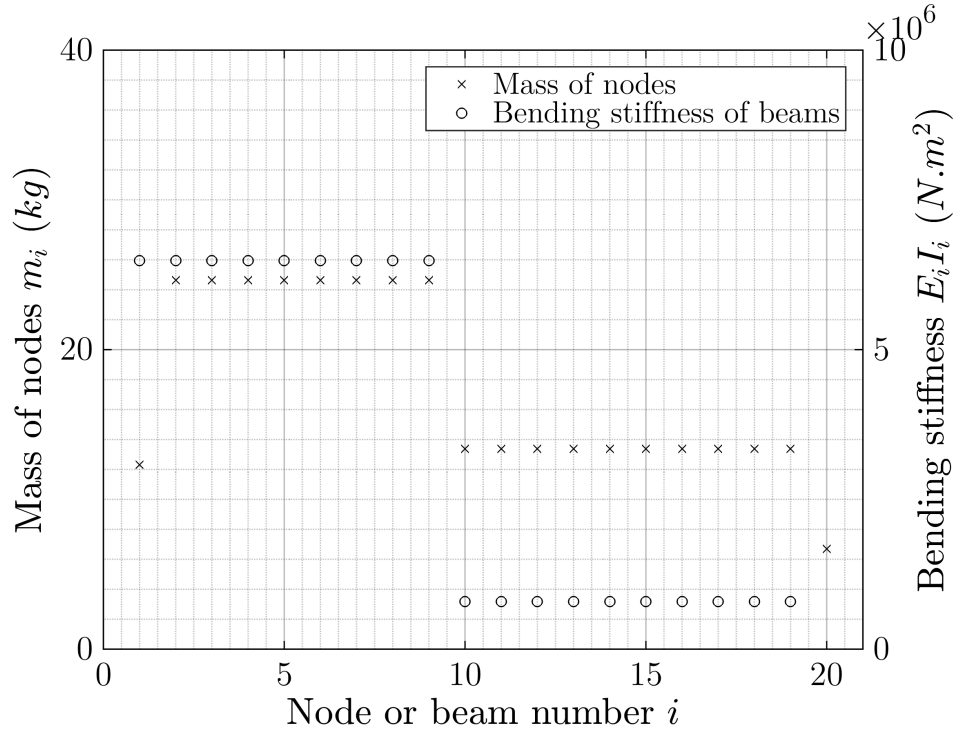

Figure 4: Summary of Structural Parameters for 20 Nodes

External efforts On each node i , an external force F_i along the z-axis and an external moment $M_{y,i}$ along the y-axis are applied.

1.2 Second-Order Structural Model

1.2.1 Nodal Model

To generate a second-order structural model, Prentis and Leckie's method [3] will be used. This finite element model can be fully characterized by the following second-order structural equation:

$$M' \ddot{u} + D' \dot{u} + K' u = F' \quad (1)$$

• $u = \begin{bmatrix} z_1 \\ \vdots \\ z_n \\ \theta_1 \\ \vdots \\ \theta_n \end{bmatrix}$ is the displacement vector

- $F' = \begin{bmatrix} F_1 \\ \vdots \\ F_n \\ M_{y,1} \\ \vdots \\ M_{y,n} \end{bmatrix}$ is the external efforts matrix
- M' is the mass matrix of this system : $M' = \begin{bmatrix} M & 0_{n \times n} \\ 0_{n \times n} & J_y \end{bmatrix}$. M and J_y are diagonal matrices containing nodes masses and rotational inertias about the y-axis.
- K' and D' are the stiffness and damping matrices of this system.

K' can be divided in four sub-matrices $K' = \begin{bmatrix} K_{11} & K_{12} \\ K_{21} & K_{22} \end{bmatrix}$. In a static situation where \ddot{u} and \dot{u} are zero, the equation 1 becomes :

$$K' u = F' \quad (2)$$

Thus

$$\begin{bmatrix} K_{11} & K_{12} \\ K_{21} & K_{22} \end{bmatrix} \begin{bmatrix} z \\ \theta \end{bmatrix} = \begin{bmatrix} F \\ M_y \end{bmatrix}$$

Finding K' To derive this matrix, one can **consider only two nodes i and $i+1$** linked with the beam i . The equation2 is simplified to:

$$\begin{bmatrix} k_{11,i} & k_{12,i} \\ k_{21,i} & k_{22,i} \end{bmatrix} \begin{bmatrix} z_i \\ z_{i+1} \\ \theta_i \\ \theta_{i+1} \end{bmatrix} = \begin{bmatrix} F_i \\ F_{i+1} \\ M_{y,i} \\ M_{y,i+1} \end{bmatrix}$$

Four cases are considered and illustrated in Figure 5:

	z_i	z_{i+1}	θ_i	θ_{i+1}
Case 1	1	0	0	0
Case 2	0	1	0	0
Case 3	0	0	1	0
Case 4	0	0	0	1

The forces and moments applied to the beam are F_i , F_{i+1} , $M_{y,i}$ and $M_{y,i+1}$. The equilibrium between external efforts on the beam gives the two equations (forces and moments at node i):

Figure 5: Elementary Cases for Two Nodes

$$F_i + F_{i+1} = 0 \quad (3)$$

$$M_{y,i} + M_{y,i+1} - l \cdot F_{i+1} = 0 \quad (4)$$

Using beam theory, the deformation and efforts are linked with the equation

$$E_i I_i \frac{\partial^2 z}{\partial x^2}(x) = -M_y(x) \quad (5)$$

where and $M_y(x) = M_{y,i+1} - (l - x) F_{i+1}$ are local young modulus, second moment of area and pitching moment at abscissa x ³. For readability purposes, $E_i I_i$ will now be noted EI_i . This yields after integration and double integration

$$EI_i \theta(x) = -\frac{1}{2} x^2 F_{i+1} + x (-M_{y,i+1} + l F_{i+1}) + A \quad (6)$$

$$EI_i z(x) = -\frac{1}{6} x^3 F_{i+1} + \frac{1}{2} x^2 (-M_{y,i+1} + l F_{i+1}) + A x + B \quad (7)$$

with A and B integration constants.

The boundary conditions are

$$\begin{cases} \theta(0) &= \theta_i \\ \theta(l) &= \theta_{i+1} \\ z(0) &= z_i \\ z(l) &= z_i \end{cases} \quad (8)$$

Thus, the system of equations 3, 4, 6, 7 and 8 for each case 1 to 4 yields :

	Case 1	Case 2	Case 3	Case 4
F_i	$12 EI_i / l^3$	$-12 EI_i / l^3$	$-6 EI_i / l^2$	$-6 EI_i / l^2$
F_{i+1}	$-12 EI_i / l^3$	$12 EI_i / l^3$	$6 EI_i / l^2$	$6 EI_i / l^2$
$M_{y,i}$	$-6 EI_i / l^2$	$6 EI_i / l^2$	$4 EI_i / l$	$2 EI_i / l$
$M_{y,i+1}$	$-6 EI_i / l^2$	$6 EI_i / l^2$	$2 EI_i / l$	$4 EI_i / l$

thus $k_{11,i}$, $k_{12,i}$, $k_{21,i}$ and $k_{22,i}$ derived from the table above are

$$\begin{cases} k_{11,i} &= \frac{12 EI_i}{l^3} \begin{bmatrix} 1 & -1 \\ -1 & 1 \end{bmatrix} \\ k_{12,i} = k_{21,i}^T &= \frac{6 EI_i}{l^2} \begin{bmatrix} -1 & -1 \\ 1 & 1 \end{bmatrix} \\ k_{22,i} &= \frac{2 EI_i}{l} \begin{bmatrix} 2 & 1 \\ 1 & 2 \end{bmatrix} \end{cases}$$

³ $x = 0$ at node i and $x = l$ and node $i + 1$

Now considering the complete missile, as the element beams are linked in serie, the matrices K_{11} , K_{12} , K_{21} , and K_{22} can be calculated by summing the matrices $k_{11,i}$, $k_{12,i}$, $k_{21,i}$ and $k_{22,i}$ on the diagonal as shown below for K_{11} :

$$K_{11} = \begin{bmatrix} k_{11,1} & & & & & \\ & k_{11,2} & & & & \\ & & k_{11,3} & & & \\ & & & k_{11,n} & & \\ & & & & k_{11,n-1} & \\ & & & & & 0 \end{bmatrix}$$

Thus, these matrices are

$$K_{11} = \frac{12}{l^3} \begin{bmatrix} EI_1 & -EI_1 & 0 & \cdots & 0 \\ -EI_1 & EI_1 + EI_2 & \ddots & \ddots & \vdots \\ 0 & \ddots & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & EI_{n-2} + EI_{n-1} & -EI_{n-1} \\ 0 & \cdots & 0 & -EI_{n-1} & EI_{n-1} \end{bmatrix}$$

$$K_{12} = K_{21}^T = \frac{6}{l^2} \begin{bmatrix} -EI_1 & -EI_1 & 0 & \cdots & 0 \\ EI_1 & EI_1 - EI_2 & \ddots & \ddots & \vdots \\ 0 & \ddots & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & EI_{n-2} - EI_{n-1} & -EI_{n-1} \\ 0 & \cdots & 0 & EI_{n-1} & EI_{n-1} \end{bmatrix}$$

$$K_{22} = \frac{2}{l} \begin{bmatrix} 2EI_1 & EI_1 & 0 & \cdots & 0 \\ EI_1 & 2EI_1 + 2EI_2 & \ddots & \ddots & \vdots \\ 0 & \ddots & \ddots & \ddots & 0 \\ \vdots & \ddots & \ddots & 2EI_{n-2} + 2EI_{n-1} & EI_{n-1} \\ 0 & \cdots & 0 & EI_{n-1} & 2EI_{n-1} \end{bmatrix}$$

It is worth noting that $K' = K'^T$ that can be explained by Maxwell-Betti reciprocal work theorem.

Simplified second-order structural model In this study, we assume that the pure external moments $M_{y,i}$ are negligible when compared to moments created by the forces F_i . The missile is modeled as an Euler-Bernoulli beam, thus the local rotational inertias I_i are zero. The damping D' is very few for such flexible structures so it can

be neglected for the next trick. With these hypotheses, the lower part of Equation 1 concerning rotational acceleration becomes :

$$0_{n \times 1} \ddot{\theta} + 0_{n \times 1} \dot{\theta} + K_{21}z + K_{22}\theta = 0_{n \times 1}$$

K_{22} is a symmetric tridiagonal matrix which invertibility can be proven by LU decomposition[1]. This leads to the important relation between z and θ :

$$\theta = -K_{22}^{-1} K_{21}z \quad (9)$$

This equation mean that the second part of u can be entirely determined from its first part. The upper part of the Equation 1 fully describes the structural system:

$$M \ddot{z} + D \dot{z} + (K_{11} - K_{12}K_{22}^{-1}K_{21}) z = F$$

The stiffness matrix is then $K = K_{11} - K_{12}K_{22}^{-1}K_{21}$. One can verify that $K^T = K$.

The damping matrix is chosen proportionnal to K and set to damp the first structural mode to 1%. This gives $D = K/6000$. The second-order structural equation is as follows:

$$M \ddot{z} + D \dot{z} + K z = F \quad (10)$$

1.2.2 Modal Model

The triplet (M, D, K) is the nodal realization of the second-order structural model. A modal realization must be found to extract the flexible body modes from the structural model. The transformation of the nodal model is described in [2] and can be derived as follows.

Considering free vibrations without damping, the system being linear, the displacement vector will be $z = \phi e^{j\omega t}$ with ϕ constant thus $\ddot{z} = -\omega^2 \phi e^{j\omega t}$ and Equation 10 becomes:

$$(-\omega^2 M + K) \phi = 0 \quad (11)$$

Non-trivial solutions to Equation 11 (i.e. $\phi \neq 0$) exist if and only if

$$\det(-\omega^2 M + K) = 0$$

The solutions are the generalized eigen values $(\omega_1^2, \omega_2^2, \dots, \omega_n^2)$ of the matrices K and M . $(\omega_1, \omega_2, \dots, \omega_n)$ are the natural frequencies of the structure and the eigen vectors $(\phi_1, \phi_2, \dots, \phi_n)$ are the natural modes also called modes shape.

In this particular study, the structure extremities are free hence the two first natural frequencies are 0 Hz and the two first natural modes correspond to the rigid-body modes: z-axis translation and y-axis rotation. The natural frequencies and modes shape are renamed $(0, 0, \omega_1, \omega_2, \dots, \omega_{n-2})$ and $(\phi_{0,1}, \phi_{0,2}, \phi_1, \phi_2, \dots, \phi_{n-2})$.

Figure 6: Modes Shape of ASTER-30

The modes shape of the rigid-body and the first three bending modes are plotted in Figure 6. This figure shows that the dart is likely to bend more than the booster. Indeed, the front part of the missile is more flexible so it will bend more.

The natural frequencies for the first modes are summarized in Table 1.

Let $\Phi = [\phi_{0,1} \ \phi_{0,2} \ \phi_1 \ \phi_2 \ \dots \ \phi_{n-2}]$ be the modal matrix and

$$\Omega = \begin{bmatrix} 0 & & & 0 \\ & 0 & & \\ & & \omega_1 & \\ & & & \ddots \\ 0 & & & & \omega_{n-2} \end{bmatrix}$$

be the matrix of natural frequencies.

Let z_m be the displacement vector of modes defined by $z = \Phi z_m$. The modal matrices of mass M_m , damping D_m and stiffness K_m are obtained as follows

$$M_m = \Phi^T M \Phi$$

$$D_m = \Phi^T D \Phi$$

$$K_m = \Phi^T K \Phi$$

Mode	Frequency	
	(Hz)	(rad.s ⁻¹)
z translation mode	0	0
y rotation mode	0	0
1 st bending mode	20.0	125
2 nd bending mode	67.7	425
3 rd bending mode	139.7	877
4 th bending mode	213.9	1344
5 th bending mode	335.1	2106

Table 1: Natural Frequencies of Modes

The triplet (M_m, D_m, K_m) defines the second-order structural modal model of the missile. The equation 10 becomes:

$$M_m \ddot{z}_m + D_m \dot{z}_m + K_m z_m = \Phi^T F \quad (12)$$

1.2.3 Output equation

Three types of sensors are investigated in this paper to measure vibrations: strain gages, gyrometers and accelerometers. Their measurement can be represented by the output equation:

$$y = C_{oz}z + C_{ov}\dot{z} + D_oF \quad (13)$$

where y is a vector containing the measurement of all sensors.

It means that the signal measured by the sensors are a linear combination of the displacement of the nodes (matrix C_{oz}), their speed (matrix C_{ov}) and also a feedforward term D_o on the external forces applied on the nodes.

Gyrometer A gyrometer on node i measures $\dot{\theta}_i$, thus n gyrometers can be placed. Since q is often used to represent the pitch rate, this letter will be used for gyrometer output matrices. According to Equation 9, $\theta = -K_{22}^{-1}K_{21}z$, therefore $\dot{\theta}_i = -K_{22}^{-1}K_{21}\dot{z}$. This yields the output matrices

$$C_{ozq} = 0_{n \times n} \quad C_{ovq} = -K_{22}^{-1}K_{21} \quad \text{and} \quad D_{oq} = 0_{n \times n}$$

Accelerometer An accelerometer on node i measures \ddot{z}_i . The letter assigned to acceleration measurement will be a like “acceleration” and the measurement will be called a_z . With an accelerometer on each node, there are n accelerometers. In Equation 13, \ddot{z} does not appear. But using the second-order structural equation 10:

$$\ddot{z} = -M^{-1}Kz - M^{-1}D\dot{z} + F$$

thus

$$C_{oza} = -M^{-1}K \quad C_{ova} = -M^{-1}D \quad \text{and} \quad D_{oa} = Id_n$$

Strain gage For a strain gage, a first order Taylor developpement to approximate the spatial derivative of $\theta(x)$ at node i will be conducted. This approximation cannot be made on nodes 1 and n therefore, only $n - 2$ strain gages are considered. The letter used for this sensor is ε which is often assigned to strains.

The Euler-Bernoulli beam theory assumes that each section stays perpendicular to the neutral axis. The strain gages are placed on the upper side of the missile therefore, the local deformation at the surface is

$$\varepsilon(x) = -\frac{\partial \theta}{\partial x} \frac{D(x)}{2}$$

where $D(x)$ is the local missile diameter. It is worth noting that $\varepsilon(x)$ is positive when the strain gage is stretched and negative when it is compressed.

The partial derivative of θ with respect to x is approximated using a first order Taylor developpement at node $i \in \llbracket 2, n-1 \rrbracket$:

$$\frac{\partial \theta}{\partial x}(x_i) \simeq \frac{\theta_{i+1} - \theta_{i-1}}{2l}$$

thus

$$\varepsilon_i = \frac{-\theta_{i+1} + \theta_{i-1}}{2l} \frac{D_i}{2}$$

Let $\varepsilon = (\varepsilon_i)_{i \in \llbracket 2, n-1 \rrbracket}$, then the previous equation yields

$$\varepsilon = T_\varepsilon \theta$$

with

$$T_\varepsilon = \frac{1}{4l} \begin{bmatrix} D_2 & 0 & -D_2 & & & & 0 \\ & D_3 & 0 & -D_3 & & & \\ & & D_4 & 0 & -D_4 & & \\ & & & \ddots & \ddots & \ddots & \\ & & & & D_{n-2} & 0 & -D_{n-2} \\ 0 & & & & & D_{n-1} & 0 & -D_{n-1} \end{bmatrix}$$

Finally, using Equation 9, the relation becomes

$$\varepsilon = -T_\varepsilon K_{22}^{-1} K_{21} z$$

hence

$$C_{oz\varepsilon} = -T_\varepsilon K_{22}^{-1} K_{21} \quad C_{ov\varepsilon} = 0_{(n-2) \times n} \quad \text{and} \quad D_{o\varepsilon} = 0_{(n-2) \times n}$$

Concatenation The output vector corresponding to the concatenation of all mea-

surements is $y = \begin{bmatrix} \varepsilon \\ q \\ a_z \end{bmatrix}$. Therefore

$$C_{oz} = \begin{bmatrix} C_{oz\varepsilon} \\ C_{ozq} \\ C_{oza} \end{bmatrix} \quad C_{ov} = \begin{bmatrix} C_{ov\varepsilon} \\ C_{ovq} \\ C_{ova} \end{bmatrix} \quad \text{and} \quad D_o = \begin{bmatrix} D_{o\varepsilon} \\ D_{oq} \\ D_{oa} \end{bmatrix}$$

Modal output matrix The Output Equation 13 will finally be

$$y = C_{oz}\Phi z_m + C_{ov}\Phi \dot{z}_m + D_o F$$

defining the modal equivalent of the output matrices :

$$y = C_{mz}z_m + C_{mv}\Phi \dot{z}_m + D_o F$$

with

$$\begin{cases} C_{mz} &= C_{oz}\Phi \\ C_{mv} &= C_{ov}\Phi \end{cases}$$

1.3 Rigid-body Modes Elimination

The second-order structural model and its output equation in there modal forms have been derived. However, the two rigid-body modes - translation and rotation - must be eliminated. Indeed, this Chapter aims at modeling only vibrations during the flight. The rigid-body dynamics modeled have been derived isolated from gravity and air and do not reflect flight dynamics hence they must be suppressed to keep only vibrations dynamics.

The matrices M_m , D_m and K_m are diagonal meaning that there is no interaction between modes in Equation 12. The rigid-body modes are eliminated by erasing the two first rows of Φ . Hence it is now $\Phi = [\phi_1 \phi_2 \dots \phi_{n-2}]$ and z_m only contains structural modes displacement. By doing so, modal mass, damping and stiffness matrices size is now $(n-2) \times (n-2)$.

Looking at the output Equation 13, truncating the rigid-body modes will remove rigid-body pitch rate and strain measurement is not influenced by rigid-body modes. However, great care must be taken for the acceleration measurement as $D_{oa} \neq 0$. To compute the acceleration measurements only due to the vibrations, the acceleration measurements due to the rigid-body modes will be calculated considering a rigid structure.

If the missile is considered as a solid, the equation of lateral acceleration at the center of gravity is:

$$a_{z,CG} = \frac{1}{m} F_z$$

and the equation of rotational acceleration is

$$\ddot{\theta} = \frac{1}{J_{y,CG}} M_{y,CG}$$

where F_z is the sum of external forces along the z-axis, $M_{y,CG}$ is the sum of moments applied at the center of gravity along the y-axis, m and J_y are the mass and rotational inertia about the center of gravity along the y-axis. The force and moments are:

$$F_z = \sum_{j=1}^n F_j$$

$$M_{y,CG} = \sum_{j=1}^n (x_{CG} - x_j) F_j$$

The acceleration at each node i is

$$a_{z,i} = a_{z,CG} + (x_{CG} - x_i) \ddot{\theta}$$

Hence, it yields

$$a_{z,i} = \frac{1}{m} \sum_{j=1}^n F_j + (x_{CG} - x_i) \frac{1}{J_y} \sum_{j=1}^n (x_{CG} - x_j) F_j$$

In matrix formulation,

$$a_{z,rb} = D_{oa,rb} F$$

where

$$D_{oa,rb} = \frac{1}{m} Id_n + \frac{1}{J_y} \begin{bmatrix} x_{CG} \\ x_{CG} - l \\ \vdots \\ x_{CG} - (n-2)l \\ x_{CG} - (n-1)l \end{bmatrix} \begin{bmatrix} x_{CG} & x_{CG} - l & \dots & x_{CG} - (n-2)l & x_{CG} - (n-1)l \end{bmatrix}$$

Finally, the output matrix $D_{oa,rb}$ is subtracted from D_{oa} to obtain the output matrix from vibrations only :

$$D_{oa,fb} = D_{oa} - D_{oa,rb}$$

However, this is not completely correct. Indeed, the rigid-body dynamics are different when the missile is considered as flexible. Therefore the rigid-body component in D_{oa} is not $D_{oa,rb}$. Looking at the Bode plot of the transfer function⁴ from F_1 to

⁴Established later

$a_{z,75}$ on Figure 7, with this first rigid-body subtraction technique, at $\omega = 0$, $a_{z,75}(\omega)$ is not zero (curve “a_z,fb imperfect”). This is incorrect because at $\omega = 0$, the vibrations are not excited then they should be inexistant and $a_{z,75} = 0$. Once the state space representation will be established, the good correction will be applied.

1.4 State Space Model

Previously, the second-order structural model in its modal form without the rigid-body modes has been derived. This representation is not convenient for control design. Therefore a state-space representation of this system will be created.

1.4.1 From Second-Order Model to State Space Model

The system must firstly be translated into a state space representation.

Now that the rigid-body modes are eliminated, K_m is positive-definite and we can define

$$\Omega = M_m^{-1/2} K_m^{1/2}$$

$$Z = \frac{1}{2} M_m^{-1} D_m \Omega^{-1}$$

Z is a diagonal matrix containing the modes damping ratios. For instant $Z_{3,3} = \zeta_3$ is the damping ratio of the third bending mode.

The state vector is defined as $x = \begin{bmatrix} z_m \\ \dot{z}_m \end{bmatrix}$. The input vector is $u = F$. The output vector is $y = \begin{bmatrix} \varepsilon \\ q \\ a_z \end{bmatrix}$ Thus

$$\dot{x} = A x + B u$$

$$y = C x + D u$$

with

$$A = \begin{bmatrix} 0_{(n-2) \times (n-2)} & Id_{n-2} \\ -\Omega^2 & -2Z\Omega \end{bmatrix}$$

$$B = \begin{bmatrix} 0_{(n-2) \times n} \\ \Phi^T \end{bmatrix}$$

$$C = \begin{bmatrix} C_{mz} & C_{mv} \end{bmatrix}$$

$$D = D_o = \begin{bmatrix} 0_{(n-2) \times n} \\ 0_{n \times n} \\ D_{oa,fb} \end{bmatrix}$$

Figure 7: Bode plot of F_1 to $a_{z,75}$

In the previous part, $D_{oa,fb}$ has not been clearly defined. To eliminate properly rigid-body dynamics measured by acceleration sensors, the following technique can be used. The acceleration due to rigid-body dynamics is composed of a feedforward term $D_{oa,rb}$ only. In the transfer function, this is a static gain. Thus, one can just remove this static value :

$$a_z(j\omega) = -C_{ma}(A - j\omega Id)^{-1}B + D_{oa,fb}$$

where $C_{ma} = \begin{bmatrix} C_{mza} & C_{mva} \end{bmatrix}$. At $\omega = 0$, $a_z = 0$ so $D_{oa,fb} = C_{ma}A^{-1}B$.

Thanks to this, a_z is 0 at low frequency as shown in Figure 7 (curve “a_z,fb correct”).

1.4.2 Formulation in State Space Modal Form 2

Gawronski [2] gives a convenient state space formulation of the structural system. It is the modal form 2. In this form, the state vector is

$$x_m = \begin{bmatrix} z_{m,1} \\ z_{mo,1} \\ z_{m,2} \\ z_{mo,2} \\ \vdots \\ z_{m,(n-2)} \\ z_{mo,(n-2)} \end{bmatrix}$$

where $z_{mo,i} = \zeta_i z_{m,i} + \dot{z}_{m,i}/\omega_i$. In this form, the modal state matrix A_m has the particular form:

$$A_m = \begin{bmatrix} A_{m1} & & & \\ & A_{m2} & & \\ & & \ddots & \\ & & & A_{m(n-2)} \end{bmatrix}$$

with $A_m = \begin{bmatrix} -\zeta_i \omega_i & \omega_i \\ \omega_i & -\zeta_i \omega_i \end{bmatrix}$.

The transformation matrix V_m defined as $x = V_m x_m$ for 4 modes is

$$V_m = \begin{bmatrix} 1 & 0 & & & & \\ & & 1 & 0 & & \\ & & & & 1 & 0 \\ & & & & & 1 & 0 \\ -\omega_1/\zeta_1 & \omega_1 & & & & & \\ & & -\omega_2/\zeta_2 & \omega_2 & & & \\ & & & & -\omega_3/\zeta_3 & \omega_3 & \\ & & & & & & -\omega_4/\zeta_4 & \omega_4 \end{bmatrix}$$

Hence, $B_m = BV_m$, $C_m = CV_m$ and $D_m = D$.

This final state-space realization (A_m, B_m, C_m, D_m) is the modal state-space model of the vibrations of the missile with outputs y containing $n - 2$ strain measurements ε_i , n gyrometer measurements q_i and n accelerometers a_{zi} . This vibrations model will then be added to the flight dynamics model.
